

Train Booking System – Project Description

This project is the development of a **Train Booking System**, a web-based platform designed to facilitate convenient intercity train travel across Egypt.

The system's core function is to allow **Registered Users** (Passengers) to seamlessly book one-way or round-trip tickets. A key feature is the **real-time train tracking** functionality, which provides live location status, an ETA, and a departure countdown. For premium services (VIP, First/Second Class), the system offers **seat selection**.

It will operate as a standalone system built on **ASP.NET Core (C#)** and **SQL Server**, ensuring a secure, responsive, and high-performance user experience in both English and Arabic. The platform integrates with necessary third-party services, including a secure **online payment gateway** and **GPS/location APIs** for accurate tracking data.

The system also supports distinct **Admin** and **Assistant Driver** user roles for managing schedules, monitoring trains, and updating passenger status. This comprehensive solution aims to significantly enhance the efficiency and overall user experience of railway booking and travel.
